

SKF spherical roller bearings

Setting the standard for performance and reliability

Contents

The SKF® brand now stands for more than ever before, and means more to you as a valued customer.

While SKF maintains its leadership as the hallmark of quality bearings throughout the world, new dimensions in technical advances, product support and services have evolved SKF into a truly solutions-oriented supplier, creating greater value for customers.

These solutions encompass ways to bring greater productivity to customers, not only with breakthrough application-specific products, but also through leading-edge design simulation tools and consultancy services, plant asset efficiency maintenance programmes, and the industry's most advanced supply management techniques.

The SKF brand still stands for the very best in rolling bearings, but it now stands for much more.

Economical and robust

A

Why spherical roller bearings?

Spherical roller bearings offer an attractive combination of design features, which are making them irreplaceable in many demanding applications.

- **Self-aligning**

Spherical roller bearings accommodate misalignment between the shaft and housing without increasing friction or reducing bearing service life.

- **Very high load carrying capacity**

Optimized internal geometry within the available cross section provides maximum radial and axial load carrying capacity.

- **Robust**

Insensitive to misalignment caused by shaft or housing deflections as a result of heavy loads.

- **Easily fitted for loads in all directions**

The bearings are non-separable and ready to install, having a choice of mounting methods.

- **Simplify the application**

The favourable design characteristics combined with simplified mounting procedures enable more efficient and compact machine designs.

Spherical roller bearings with integral seals offer additional benefits.

- **Protect against contaminants**

Sealed spherical roller bearings are especially suited for bearing positions where space or cost considerations make external seals impractical.

- **Grease retention**

A contact seal on both sides of the bearing retains the factory grease fill where it is required: inside the bearing.

- **Minimized maintenance requirements**

Under normal operating conditions, sealed spherical roller bearings are maintenance-free, keeping service costs and grease consumption low.

Why SKF spherical roller bearings?

SKF bearings are developed for customer satisfaction. The best confirmation of the total quality of SKF spherical roller bearings is their success on the market. There are twice as many SKF spherical roller bearings in service as those of any other bearing manufacturer.

This is not just by chance: SKF spherical roller bearings are well-proven in the field and undergo continuous development to provide improved performance. Recent examples include the introduction of SKF Explorer™ bearings, which opened up new application horizons, and sealed bearings.

The use of SKF spherical roller bearings implies several benefits.

Application efficiencies

SKF spherical roller bearings have a very high load carrying capacity in the radial and axial directions. Bearing applications become increasingly cost effective due to

- long service life
- compact arrangements.

Reduced operating costs

The optimized and robust internal design of SKF spherical roller bearings minimizes friction and heat, and by this, lubricant consumption. In service, this reduces costs due to

- less machine downtime
- minimized maintenance requirements
- high reliability.

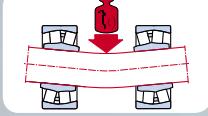

Seals integration

Under normal operating conditions, sealed SKF spherical roller bearings are greased for life and make external seals unnecessary, creating additional benefits

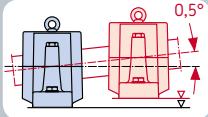

- simplified bearing arrangements
- no relubrication.

Standard solution

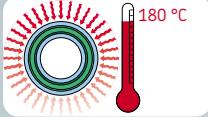

Many bearing applications previously fitted with expensive special bearings can now be equipped with SKF spherical roller bearings. Because of the global availability of SKF spherical roller bearings, delivery is not a problem!

Rugged

Accommodate misalignment

Resistant to high temperatures

Customer satisfaction

Equipment owners will be impressed by the low operating costs in combination with high reliability contributed by SKF spherical roller bearings. Not only are costs reduced, but with sealed versions environmental resources are spared.

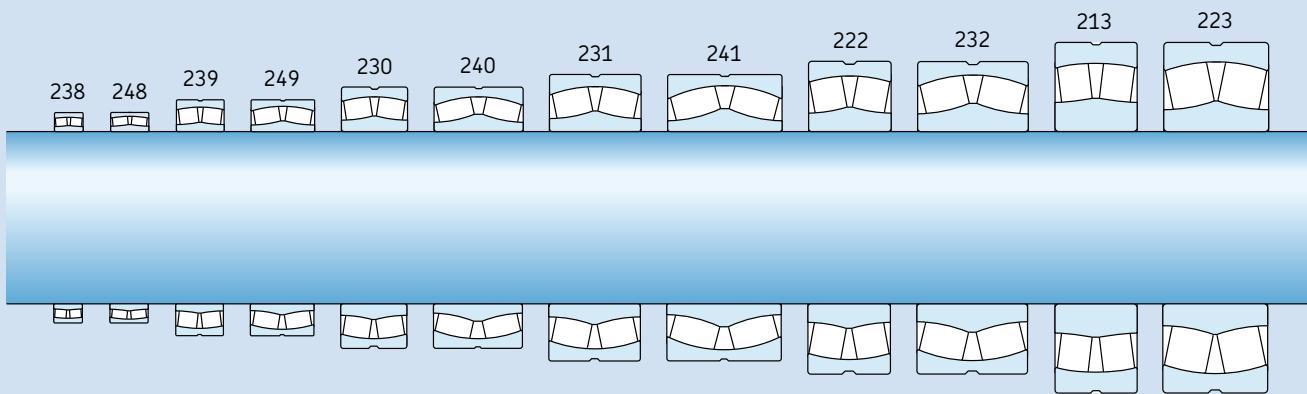

A

*SKF spherical roller bearings:
Always the best choice, when robustness and
reliability matter*

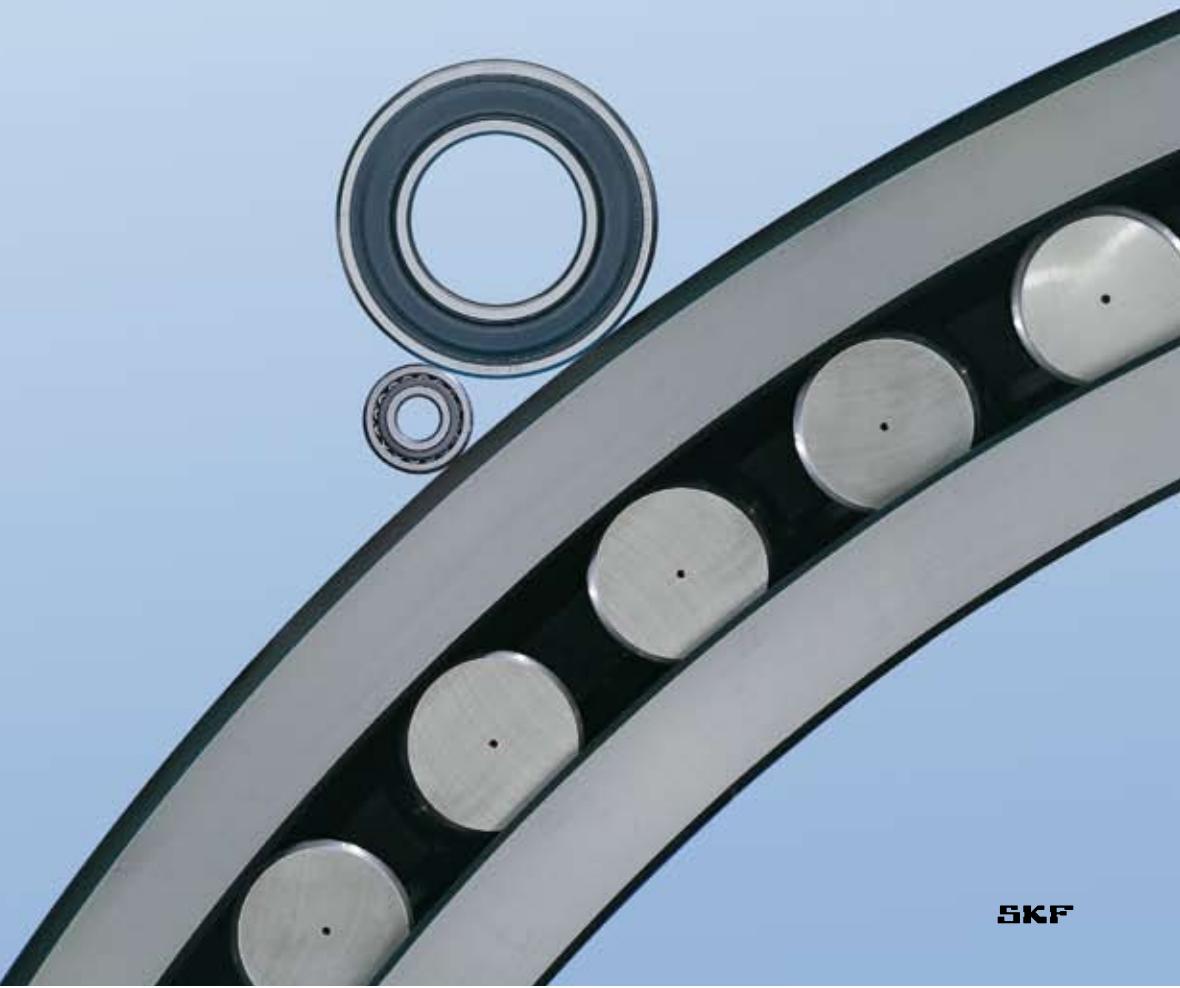

Spherical roller bearing series (open design)

A complete bearing range

The range of open and sealed SKF spherical roller bearings covers all series currently in demand. Taking availability into account, this constitutes the most complete range on the market.

Narrow low-section bearings have better speed, space and weight characteristics. Wide high-section bearings have higher load carrying capacity.

SKF spherical roller bearings without seals

Open bearings are available in sizes from 20 to 1 800 mm bore diameter with either a cylindrical or tapered bore to suit all mounting methods. To facilitate efficient lubrication, most bearings are provided with an annular groove and three lubrication holes in the outer ring.

The bearings are available in a wide number of series designed to satisfy the following selection criteria

- load carrying capacity
- combination of radial and axial loads
- rotational speed
- available space in the application.

Sealed SKF spherical roller bearings

SKF sealed spherical roller bearings are available with a cylindrical bore for shaft diameters ranging from 35 to 220 mm. Bearings with a tapered bore are available for shaft diameters from 40 to 90 mm. Additional sizes can be produced to special order.

The seals, specially developed for spherical roller bearings, effectively prevent contaminants from entering into the rolling contact area. This is not only true in operation, but also during bearing installation, resulting in long service life.

SKF spherical roller bearings – leading in design

Standard bearings: a unique combination of design features

All SKF spherical roller bearings have features in common that are unique in the market

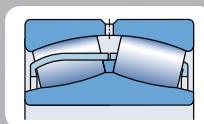

- symmetrical rollers
- special roller profile
- self-guiding rollers – an SKF patent
- floating guide ring between the two rows of rollers
- bearing components dimensionally stabilized for high temperatures
- metallic cages.

To facilitate efficient bearing lubrication SKF standard spherical roller bearings are provided with three lubrication holes in the outer ring, usually in combination with an annular groove. Depending on the series and size, standard SKF spherical roller bearings are basically manufactured to three different designs

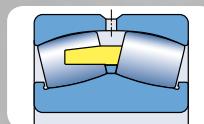

- E design
- CC design
- CA design.

E design
Consists of symmetrical rollers, two hardened window-type steel cages centred on the flangeless inner ring via a floating guide ring between the two rows of rollers.

CC design
Consists of symmetrical rollers, two window-type steel cages centred on the flangeless inner ring via a floating guide ring between the two rows of rollers.

CA design
Consists of symmetrical rollers, a double pronged, machined brass or steel cage, centred on the inner ring via a floating guide ring between the two rows of rollers, an inner ring with retaining flanges.

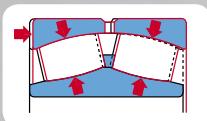

Durable cage design
Steel and brass cages are strong as well as tolerant to high temperatures and all lubricants. Small and medium size bearings have window-type steel cages, larger sizes have machined brass or steel, double pronged cages.

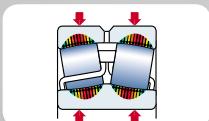

E design

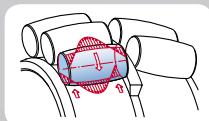

CC design

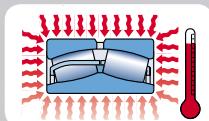

Very high load carrying capacity
The symmetrical rollers self-adjust, providing an even load distribution along the roller length. This provides very high load carrying capacity under all load combinations.

No edge stresses
The special roller profile virtually eliminates the risk of edge stresses.

Reduced friction and minimum heat generation
Self-guiding rollers – an SKF patent – mean reduced friction and minimum heat generation.

Excellent performance at high temperatures
High-strength, dimensionally stable bearing rings minimize the risk of ring cracking and also enable good performance at high temperatures.

Setting new standards: SKF Explorer

The unique SKF spherical roller bearing designs were the starting points for further development of materials and manufacturing processes. SKF Explorer spherical roller bearings are the result of the work of a very skilled team of engineers and scientists and intensive fine tuning processes, which, taken all together constitutes a new performance level for spherical roller bearings.

- **Steel**

Ultra-clean steel provides longer service life under heavy loads.

- **Heat treatment**

Unique procedures significantly improve wear-resistance and hardness.

- **Manufacturing**

Refined processes enable the production of smoother running bearings that maximize the effects of the lubricant.

- **Internal geometry**

A fine-tuned micro-geometry of the rolling contacts provides better stress distribution.

- **Running accuracy and width tolerances**

The majority of SKF Explorer spherical roller bearings are manufactured as standard to P5 tolerance class for running accuracy. This makes them outstanding on the spherical roller bearing market as well as in relation to other bearing types. A tight width tolerance contributes to simplified mounting procedures in certain applications.

SKF Explorer bearings provide better performance than a similarly sized bearing as explained in more detail from **page 12** onwards.

CA design

Sealed SKF spherical roller bearings – for demanding environments

Sealed SKF spherical roller bearings are designed to fulfil high demands on sealing efficiency and operational reliability under difficult environmental conditions. The seals were developed using computer simulations, making full use of the vast expertise within the SKF Group. They have been tested extensively in the laboratory and in the field and have a proven record of reliable performance and efficiency.

Sealed SKF spherical roller bearings include double-lip, sheet steel reinforced seals and a grease fill that is appropriate to the operating conditions.

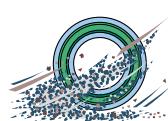

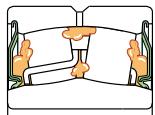

Sealed SKF spherical roller bearings are ready to mount and lubricated for life to provide long service life within, in most cases, the same space requirements as a standard open bearing. Advantages include a simplified bearing arrangement as well as the option to make the arrangement more compact. Facilities for relubrication are normally not required, eliminating the need to purchase and dispose of bearing grease.

Temperature limits

Sealed SKF spherical roller bearings are suitable for normal operating temperatures up to +110 °C (230 °F). Bearings for higher operating temperatures can be supplied upon request. In these cases, the grease and seal material must be chosen accordingly. Other operating conditions such as speed may need to be considered as well. Please contact the SKF application engineering service for additional information.

Contamination resistance

Due to the robust and efficient integral seals, additional external seals are not necessary in many applications, generally leading to more compact bearing arrangements. If the operating environment is harsh, external seals should be used (→ fig. 1).

Well lubricated

Bearings for normal operating temperatures and speeds are lubricated with SKF LGEP 2, a grease with a lithium thickener. The grease has excellent rust inhibiting properties.

Well protected

The bearings have a sheet steel reinforced double-lip seal on each side. Seals can be made of acrylonitrile-butadiene rubber (NBR), hydrogenated nitrile rubber (HNBR) or fluoro rubber (FKM).

Always reliable

The bearings are filled with a high-quality grease, which is particularly suitable for SKF spherical roller bearings. Integral seals contribute to efficient lubrication by keeping the lubricant inside the bearing.

Solid contaminants excluded

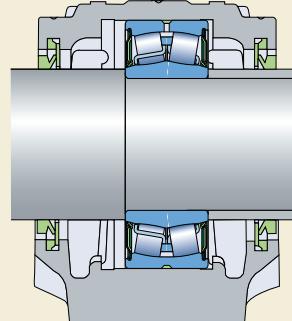

Sealed SKF spherical roller bearings provide excellent protection against contaminants. Contaminants can create indentations in raceways and rollers, resulting in flaking and premature failure. Seals also protect the bearing from contaminants during handling and mounting.

Moisture cannot enter

Adequate seals keep moisture out of the bearing, which otherwise would cause corrosion and considerable damage to the raceways, leading to noise and premature failure. The bearings are protected further by the rust inhibiting properties of the lubricant.

A sealed spherical roller bearing in an SNL plummer block housing with external seals

Fig. 1

Rule of thumb

Sealed bearings do not need relubrication when

- temperatures do not exceed +70 °C (158 °F)
- the inner ring rotates
- speeds are not more than 50 % of the limiting speeds listed in the product tables.

Additional information can be found in the section "Lubrication and maintenance" starting on page 24.

SKF spherical roller bearings for vibratory applications

For machines with inherent eccentric motion such as vibrating screens and compactors, SKF developed the range of standard spherical roller bearings for vibratory applications. The bearings are available in the 223 series with either a cylindrical or tapered bore for shaft diameters ranging from 40 to 240 mm.

Bearings with the current basic designs have been in service for more than a decade and have been shown to considerably reduce operating temperatures and extend service life of the machinery.

Reinforced for tough operating conditions

The standard bearings for vibratory applications have a special clearance and are modified to cope with the shaft deflections encountered in vibratory applications. They are characterized by a hardened floating guide ring generally centred in the outer ring that guides the highly wear-resistant, surface-hardened window-type steel cages.

The dull-yellowish coloured cages make them distinguishable from bearings for standard applications (→ fig. 2).

To prevent fretting corrosion at the non-locating bearing position, a special version with a PTFE-coated cylindrical bore is available.

Vibratory applications induce accelerations of the rollers and cages in the bearings. These accelerations put additional demands on the bearing and can cause a bearing for standard applications to fail prematurely. SKF spherical roller bearings for vibratory applications are designed to withstand these induced accelerations. The permissible acceleration depends on the lubricant and whether the acceleration is rotating or linear.

Rotating acceleration

This type of acceleration is created in a bearing subjected to a rotating outer ring load and a rotating acceleration field. This generates cyclic loads on the cages from the unloaded rollers. Typical examples are vibrating screens and planetary gears. Road rollers are subject to a mix of rotating and linear accelerations (→ fig. 3a).

Linear acceleration

Linear acceleration occurs when a bearing is subjected to impact loads that hammer the cages. A typical linear acceleration is generated when rail wheels are rolling over rail joints (→ fig. 3b). An analogous application using bearings for vibratory applications is a road roller where the roller is vibrating against a relatively hard surface.

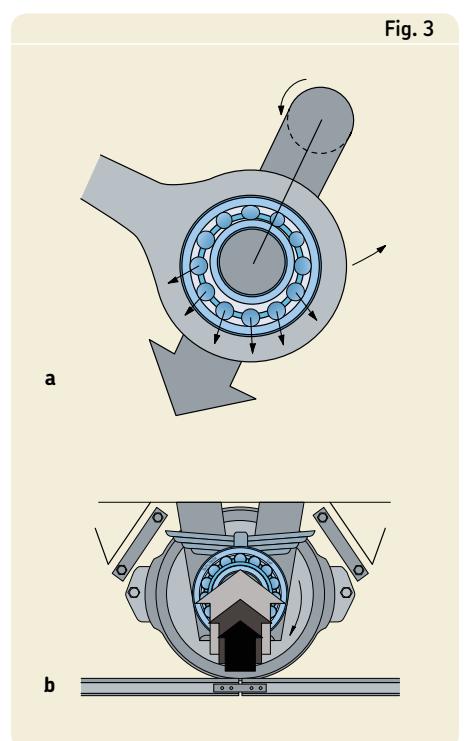

SKF spherical roller bearings for vibratory applications offer decisive benefits:

- Excellent performance in all types of vibratory machinery.
- SKF Explorer performance provides an opportunity to design more compact arrangements.
- Excellent wear-resistant characteristics, even in contaminated environments

Designs

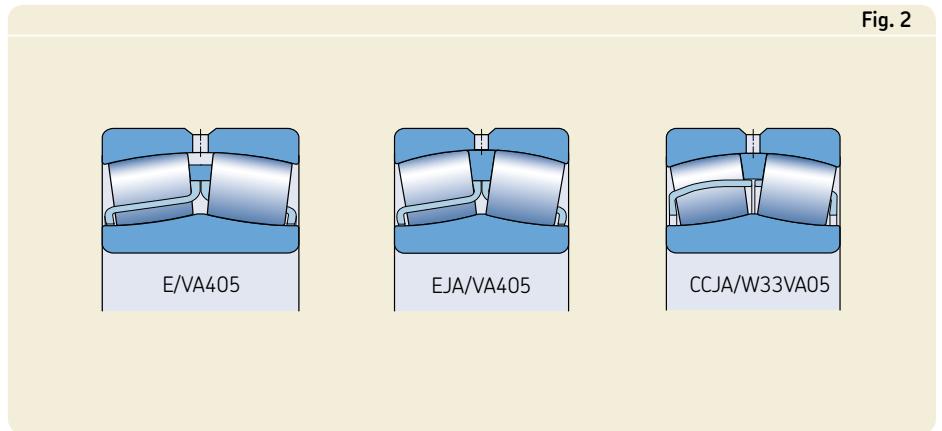

Depending on their size, SKF spherical roller bearings for vibratory applications incorporate one of the following internal designs:

- E/VA405 consists of symmetrical rollers, two hardened window-type steel cages centred on the inner ring and a floating guide ring outside the cages.
- EJA/VA405 consists of symmetrical rollers, two hardened window-type steel cages centred on the outer ring via a floating guide ring between the two roller rows.
- CCJA/W33VA405 consists of symmetrical rollers, two hardened window-type steel cages centred on the outer ring via a floating guide ring between the two roller rows.

Example of a bearing subjected to rotating acceleration (a) and linear acceleration (b)

SKF Explorer – the new performance class for spherical roller bearings

Having invented the spherical roller bearing more than 80 years ago, SKF has been the leading manufacturer of these bearings ever since.

Recently, SKF specialists from different disciplines combined their knowledge and experience to take one large step forward in bearing technology. And we are proud of having made tomorrow's bearing technology available for our customers today. SKF Explorer bearings represent a significant breakthrough in performance. By studying the interrelationship between each bearing component, SKF scientists were able to maximize the effects of the lubricant and minimize the effects of friction, wear, and contamination.

Bearings in the SKF Explorer performance class incorporate a number of improvements including:

The material

The steel used in SKF Explorer bearings is extraordinarily clean and homogeneous. It forms an excellent structure which does not generate stress peaks under load.

A unique heat treatment

Together with a refined heat treatment process, the new steel significantly improves the wear-resistance of SKF Explorer bearings. It does this while retaining the temperature resistance and toughness of the bearings.

Improved manufacturing processes

Improved manufacturing processes have enabled SKF to maintain tighter tolerances on all critical bearing parameters. To further improve bearing performance, the finish of all contact surfaces has been maximized to maintain an optimum oil film.

Bearing knowledge

Sophisticated, proprietary software has enabled SKF design engineers to study internal bearing dynamics to an extent not possible previously. This has led the way to refinements, which have been incorporated into SKF Explorer bearings, to further optimize the rolling element/raceway contacts.

The result: longer bearing service life

All these improvements contribute to a significant increase in bearing service life and reliability. This can best be shown through calculation using the SKF rating life equation. The properties of SKF Explorer spherical roller bearings are taken into consideration by

- increased basic dynamic load ratings
- an increased life adjustment factor a_{SKF}

Availability

The range of high performance SKF Explorer spherical roller bearings is the widest among corresponding bearings on the market.

In the product tables, the designations of SKF Explorer bearings are printed in blue.

Product designations

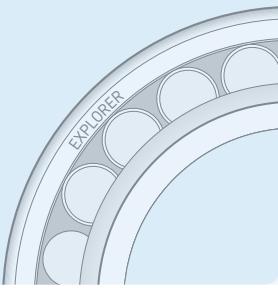

SKF Explorer bearings retain the designations of earlier standard bearings, e.g. 22218 E or BS2-2210 C-2CS. However, each bearing and its box is marked with the name EXPLORER, so that there can be no confusion.

Existing machine

Switching to SKF Explorer bearings provides

- several times the service life previously achieved
- more machine uptime
- higher safety factor
- an appreciable reduction of machine cycle cost

and, therefore, added value.

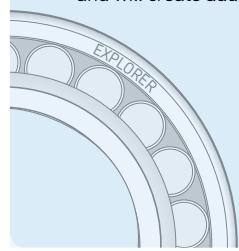

New machine with same power

SKF Explorer bearings make it possible to use a smaller bearing size to provide

- more compact machines
- higher speeds
- smoother and quieter running
- less lubricant usage
- reduced friction

and will create added value.

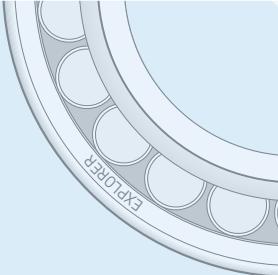

Existing machine with increased power

Same size SKF Explorer bearings enable power increases of 15 to 25 % with

- same service life
- same machine uptime
- same machine design

and higher added value.

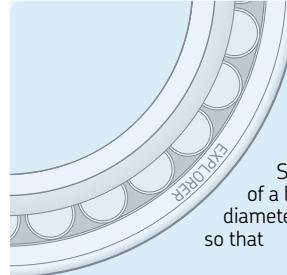

New machine with same or increased power

The higher load carrying capacity of SKF Explorer bearings enable the use of a lighter series with the same outside diameter and increased bore diameter, so that

- a stronger, or even hollow shaft can be used
- the total design can be stiffer and also more cost-effective
- system life is increased due to higher stiffness

and machine cycle cost is significantly reduced.

Efficient in all industrial segments

Industrial segments

- Metallurgical
- Mining and construction
- Fluid machinery
- Material handling
- Industrial gearboxes
- Textile industry
- Railways
- Energy

Requirements

- Long service life
- High load carrying capacity
- Compact arrangements
- Accommodate misalignment
- Minimum maintenance
- Reduced operating costs
- Fewer unplanned stops
- Environmental sustainability
- High availability
- Technical support

Solution

Long service life, high reliability, minimized maintenance and the ability to design compact arrangements have made SKF spherical roller bearings indispensable in many industries. In addition to the industrial segments listed above, SKF spherical roller bearings are also used in bridges, dam gates, electric motors, generators, plastic calenders, extruders, printing machines, robots and many other applications.

Because end users are recognizing that high quality bearings deliver an excellent return on investment, SKF spherical roller bearings have become the preferred choice in new applications.

Where maintenance can be a nightmare

To get to the top is always a challenge, particularly if the goal is the top of ski-lift masts in midwinter when it is 30 degrees below zero and the bearings have to be relubricated. If operational reliability is to be achieved, then it has to be done. Regular relubrication is a must if the bearings are to be kept from rusting because of condensation. In addition, safety considerations call for regular inspections – a dangerous job high up in mountainous terrain and under difficult weather conditions.

The introduction of SKF sealed spherical roller bearings has made all the difference. It is now only necessary to perform maintenance once a season – before starting operation. The highly efficient seals reliably exclude condensation so that corrosion is no longer a problem. It has also been possible to simplify the arrangement, saving space and costs – as well as making handling and installation easier.

Downsizing – more than just size

A typical application for spherical roller bearings is the winch of a traversing industrial lift. In this application the loads, deflections and structural deformations call for rugged bearings that can function properly even under misalignment.

Arrangements with open spherical roller bearings provided good service, but were too bulky and complicated to be considered completely satisfactory.

As a result, the open bearings were replaced with SKF sealed spherical roller bearings, eliminating the need for external seals and covers.

This obviously saved space and also meant that the bearings could be positioned 40 % closer to the drum, thus reducing shaft stresses. In fact, it was possible to reduce the shaft diameter by 20 % and use smaller bearings.

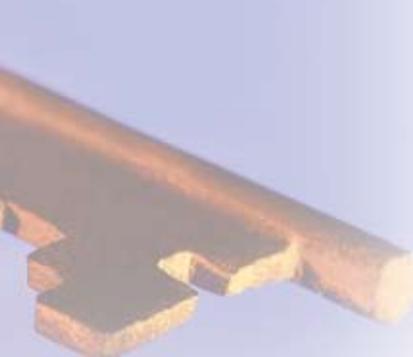

The new compact bearing arrangement needs only minimal maintenance and there is no loss of load lifting capacity. The result was a 50 % savings of the total cost of the original bearing arrangement.

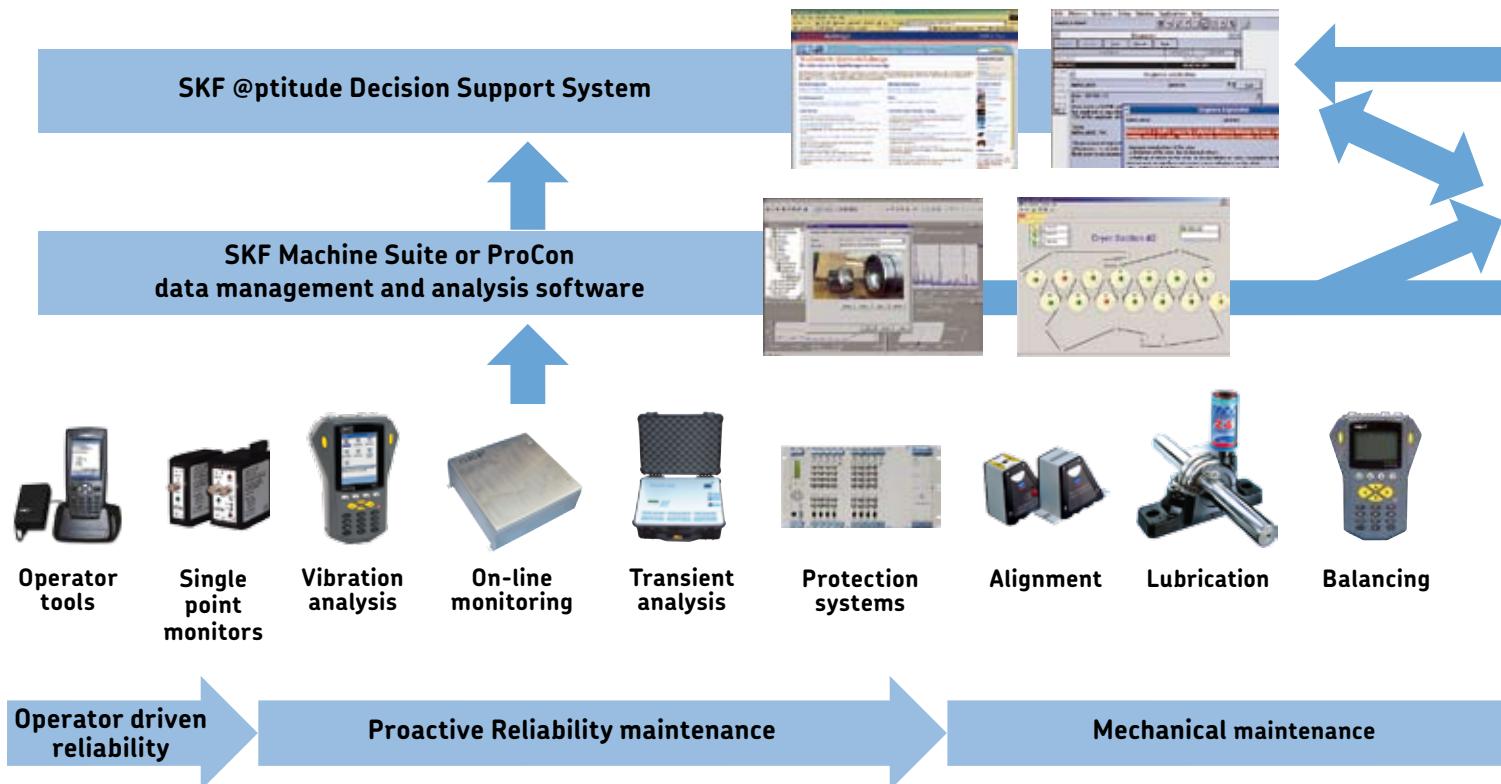

A

Service for a lasting partnership

Integrated platform for asset efficiency optimization

SKF Reliability Systems offers data acquisition hardware, condition monitoring software, decision support systems, and reliability and logistics services.

Based on 100 years of experience with rotating equipment, SKF's expertise begins at the component level and extends to a deep understanding of the technologies required to improve manufacturing processes.

Using this knowledge, SKF can work with you to design more efficiency into your machines and then provide maintenance solutions to keep those machines in peak operating condition.

The result? Improved customer satisfaction – and reduced returns under warranty.

A

SKF concepts for creating customer value

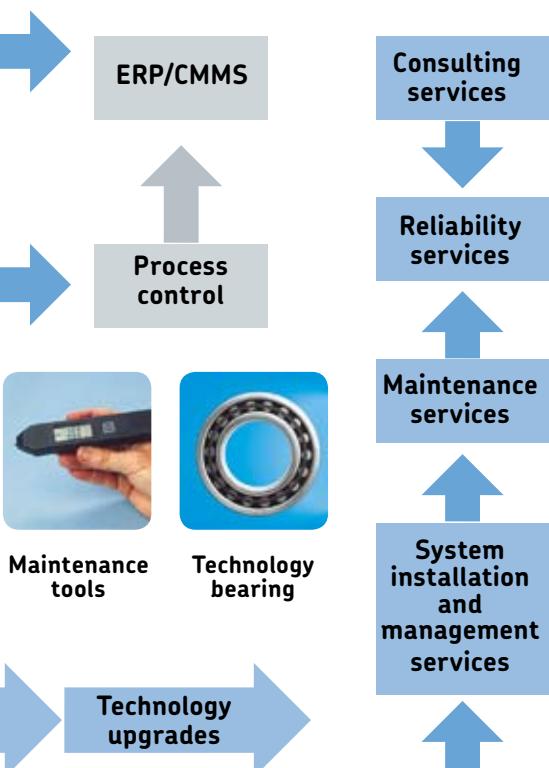

With experience in virtually every industrial sector, SKF can provide solutions that go beyond simple maintenance to improve machine performance and productivity. With our Total Shaft Solutions™ concept customers can take full advantage of our in-depth competence including, but not limited to

- root cause failure analysis
- maintenance assessments
- predictive and preventive maintenance
- lubrication and filtration management
- equipment maintenance and monitoring – fans, pumps, gearboxes and spindles
- precision balancing
- precision alignment
- applications-specific training
- component and technology upgrades
- installation and repair services.

Another SKF concept that embraces a broader view of improving machine reliability is called Asset Efficiency Optimization (AEO). As the name implies, AEO recognizes the importance of treating machinery and equipment as plant assets. SKF programmes that take a systems approach to managing these assets include

- Proactive reliability maintenance
- Operator driven reliability
- Integrated Maintenance Solutions, which include all-inclusive contractual programmes.

For more information about SKF competencies and services contact your local SKF representative.

SKF uses its own product, service and knowledge capabilities, in combination with other providers, to implement a complete reliability programme based on specific business goals.

Selection of bearing size

Bearing life

The life-extending improvements embodied in SKF Explorer spherical roller bearings can best be understood using the SKF rating life equation. This calculation method constitutes an extension of the fatigue life theory developed by Lundberg and Palmgren and is better able to predict bearing life. The SKF rating life equation was presented in the SKF General Catalogue 6000 and is in accordance with ISO 281:1990/Amd 2:2000. The equation to be used for roller bearings is

$$L_{nm} = a_1 a_{SKF} L_{10}$$

or

$$L_{nm} = a_1 a_{SKF} \left(\frac{C}{P} \right)^{10/3}$$

If the speed is constant, it is often preferable to calculate the life expressed in operating hours using

$$L_{nmh} = a_1 a_{SKF} \frac{1\,000\,000}{60 n} \left(\frac{C}{P} \right)^{10/3}$$

where

L_{nm} = SKF rating life (at $100 - n^{1)}\%$ reliability), millions of revolutions

L_{nmh} = SKF rating life (at $100 - n^{1)}\%$ reliability), operating hours

L_{10} = basic rating life (at 90 % reliability), million revolutions

a_1 = life adjustment factor for reliability
(→ table 1)

a_{SKF} = SKF life modification factor
(→ diagram 1)

C = basic dynamic load rating, kN

P = equivalent dynamic bearing load, kN

n = rotational speed, r/min

The a_{SKF} factor

The a_{SKF} factor represents a very complex relationship between various influencing factors: the fatigue load limit ratio, contamination and lubrication. Values of the fatigue load limit (P_u) are provided in the tables. Lubrication conditions are expressed by the viscosity ratio κ . Values of a_{SKF} can be obtained from **diagram 1** for different values of $\eta_c (P_u/P)$ and κ .

For standard spherical roller bearings, the values in black on the x axis should be used and for SKF Explorer bearings the values in blue on the x axis should be used. In fact, for SKF Explorer spherical roller bearings it has been found appropriate to multiply $\eta_c (P_u/P)$ by a factor of 1,4 as an expression of the life extending refinements of these bearings, and the blue values correspond to this.

Diagram 1 has been drawn up for a safety factor commonly used in fatigue life considerations and is valid for lubricants without EP additives. If a lubricant containing such additives is used, reference should be made to the SKF General Catalogue or to the SKF Interactive Engineering Catalogue, available online at www.skf.com.

Equivalent dynamic bearing load

The equivalent dynamic bearing load for spherical roller bearings can be obtained from

$$P = F_r + Y_1 F_a \quad \text{when } F_a/F_r \leq e$$

$$P = 0,67 F_r + Y_2 F_a \quad \text{when } F_a/F_r > e$$

where

P = equivalent dynamic bearing load, kN

F_r = actual radial bearing load, kN

F_a = actual axial bearing load, kN

Y_1, Y_2 = axial load factors for the bearings

e = calculation factor

Appropriate values for the factors e, Y_1 and Y_2 can be found in the bearing tables for each individual bearing.

Table 1

Values for life adjustment factor a_1

Reliability %	Failure probability n %	SKF rating life L_{nm}	Factor a_1
90	10	L_{10m}	1
95	5	L_{5m}	0,62
96	4	L_{4m}	0,53
97	3	L_{3m}	0,44
98	2	L_{2m}	0,33
99	1	L_{1m}	0,21

¹⁾ The factor n represents the failure probability, i.e. the difference between the requisite reliability and 100 %

Standard and SKF Explorer – a comparison

The performance enhancements incorporated into SKF Explorer spherical roller bearings can best be demonstrated by a life calculation of a bearing 22218 E, comparing the previous standard version with the SKF Explorer bearing.

For the same operating conditions the life of

- the previous standard 22218 E with
 - a basic dynamic load rating $C = 282 \text{ kN}$, and
 - a fatigue load limit $P_u = 39 \text{ kN}$, and
- SKF Explorer bearing 22218 E with
 - a basic dynamic load rating $C = 325 \text{ kN}$, and
 - a fatigue load limit $P_u = 39 \text{ kN}$

are calculated.

The operating conditions are

- equivalent dynamic bearing load $P = 28,2 \text{ kN}$
- viscosity ratio $\kappa = 2$
- contamination factor $\eta_c = 0,4$.

The lives of the two bearings are then calculated.

Earlier standard bearing

For $\eta_c (P_u/P) = 0,4 \times 39/28,2 = 0,55$ using the black values on the x axis in **diagram 1** and $\kappa = 2$

$$a_{\text{SKF}} = 3,7$$

so that the life becomes

$$L_{10m} = a_{\text{SKF}} (C/P)^{10/3} = 3,7 \times (282/28,2)^{10/3}$$

$$L_{10m} = 7970 \text{ million revolutions}$$

SKF Explorer bearing

For $\eta_c (P_u/P) = 0,4 \times 39/28,2 = 0,55$ using the blue values on the x axis in **diagram 1** and $\kappa = 2$

$$a_{\text{SKF}} = 7,1$$

so that the life becomes

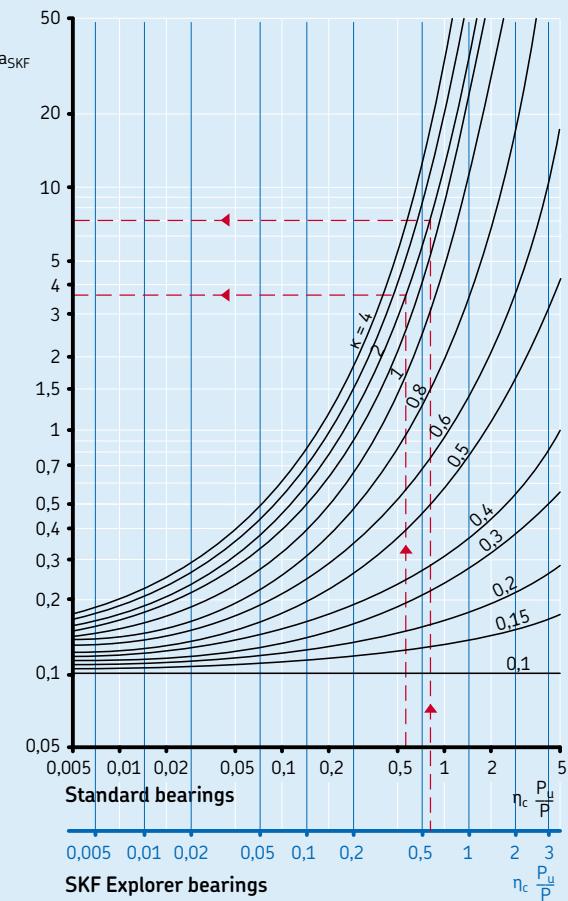

$$L_{10m} = a_{\text{SKF}} (C/P)^{10/3} = 7,1 \times (325/28,2)^{10/3}$$

$$L_{10m} = 24500 \text{ million revolutions}$$

In this case, the life of the SKF Explorer bearing can be compared with the life of the previous standard bearing by $24500/7970 = 3,07$ which is just over three times longer life.

Diagram 1

Factor a_{SKF} for spherical roller bearings

If $\kappa > 4$, use $\kappa = 4$ curve
As the value of $\eta_c (P_u/P)$ tends to zero, a_{SKF} tends to 0,1 for all values of κ

Minimum load

In order to provide satisfactory operation, spherical roller bearings, like all ball and roller bearings, must always be subjected to a given minimum load, particularly if they are to operate at high speeds or are subjected to high accelerations or rapid changes in the direction of load. Under such conditions, the inertia forces of the rollers and cage(s), and the friction in the lubricant, can have a detrimental influence on the rolling conditions in the bearing arrangement and may cause damaging sliding movements to occur between the rollers and raceways.

The requisite minimum load to be applied to spherical roller bearings can be estimated using

$$P_m = 0,01 C_0$$

where

P_m = equivalent minimum load, kN

C_0 = basic static load rating, kN

(→ product tables)

In some applications it is not possible to reach or exceed the requisite minimum load. However, if the bearing is oil lubricated lower minimum loads are permissible. These loads can be calculated

when $n/n_r \leq 0,3$ from

$$P_m = 0,003 C_0$$

and when $0,3 < n/n_r \leq 2$ from

$$P_m = 0,003 C_0 \left(1 + 2 \sqrt{\frac{n}{n_r} - 0,3} \right)$$

where

P_m = equivalent minimum load, kN

C_0 = basic static load rating, kN

(→ product tables)

n = rotational speed, r/min

n_r = reference speed, r/min

(→ product tables)

When starting up at low temperatures or when the lubricant is highly viscous, even greater minimum loads than $P_m = 0,01 C_0$ may be required. The weight of the components supported by the bearing, together with external forces, generally exceeds the requisite minimum load. If this is not the case, the spherical roller bearing must be subjected to an additional radial load.

NoWear® spherical roller bearings have been proven to provide reliable operation under very light loads. They can withstand longer periods

of inadequate lubrication, sudden variations in load and rapid speed changes

Required static load rating

The requisite basic load rating C_0 can be determined from

$$C_0 = s_0 P_0$$

where

C_0 = static load rating, kN

s_0 = static safety factor

P_0 = equivalent static bearing load, kN

Guideline values based on experience are listed in **table 2** for the static safety factor s_0 for various types of operation and requirements regarding smooth running.

The equivalent static bearing load for spherical roller bearings can be obtained from

$$P_0 = F_r + Y_0 F_a$$

where

P_0 = equivalent static bearing load, kN

F_r = actual radial bearing load, kN

F_a = actual axial bearing load, kN

Y_0 = axial load factor of the bearing

The appropriate value for the factor Y_0 can be found in the bearing tables for each individual bearing.

Are you still doing these calculations by hand?

The SKF Interactive Engineering Catalogue (available online at www.skf.com) contains all the equations and underlying software necessary to perform any of the calculations mentioned in this brochure with a click of the mouse.

Guideline values for the static safety factor s_0

B

Conventional bearing arrangements

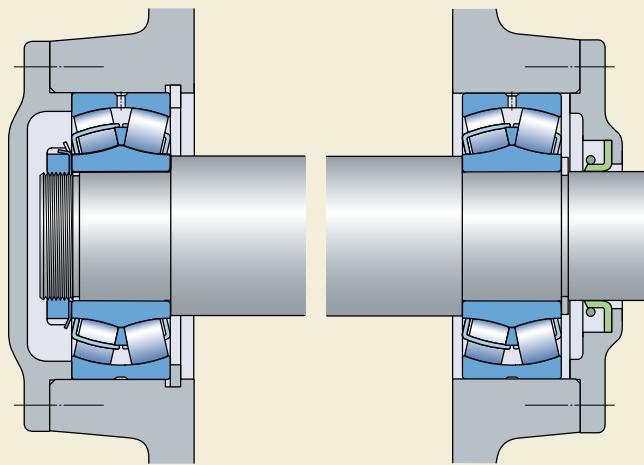

Conventional self-aligning bearing systems using spherical roller bearings in both the locating and non-locating positions, are the basis of many industrial bearing arrangements (→ fig. 1). This is a simple robust arrangement capable of withstanding heavy radial and axial loads, while easily accommodating misalignments.

The bearing in the non-locating position must be able to slide axially, usually inside the housing, to accommodate shaft expansion or

contraction. To achieve this movement, one of the bearing rings must be mounted with a loose fit and axial space provided for such movement.

Under certain loading conditions, however, this bearing arrangement may not be suitable. The ring with a loose fit can creep and damage the housing. It can also result in accelerated wear and increased vibration, additional maintenance and repair costs. It also means that the shaft is supported less rigidly in the radial direction. In these situations, the SKF self-aligning bearing system is recommended.

Fig. 1

Conventional bearing system with spherical roller bearings in both the locating position (left) and non-locating position (right)

The SKF self-aligning bearing system

The SKF self-aligning bearing system consists of a spherical roller bearing in the locating position and CARB® toroidal roller bearing in the non-locating position (→ fig. 2).

This bearing system accommodates misalignment as well as axial movement of the shaft within the CARB bearing, virtually without friction. As such, the outer rings of both bearings can have a tight fit. Furthermore, there are no induced axial loads which otherwise could be caused by the friction between the sliding outer ring and the housing seating. The bearing system only has to support external loads, which are more predictable.

The benefits of SKF spherical roller bearings and CARB bearings are fully utilized so that engineers can attain the performance characteristics they need for faster, more compact and robust designs.

The SKF self-aligning bearing system enhances reliability and performance. Producers as well as users of machines have clearly reduced costs due to simpler design and increased productivity.

Additional information can be found in the SKF brochure 4417 "Self-aligning bearing systems".

Radial location of bearings

If the load carrying ability of a bearing is to be fully utilized, its rings must be evenly supported around the circumference and across the whole width of the raceway. This support must be firm and even and can be provided by either a cylindrical or tapered seating.

Sufficient support, as well as good radial location of the bearing, generally requires a tight fit between the bearing rings and its adjacent components. However, if easy mounting and dismounting is required, or if a spherical roller bearing is in the non-locating position, a tight fit cannot be applied.

Additional information about fits and the accuracy of bearing seatings can be found in the SKF General Catalogue or online in the SKF Interactive Engineering Catalogue at www.skf.com.

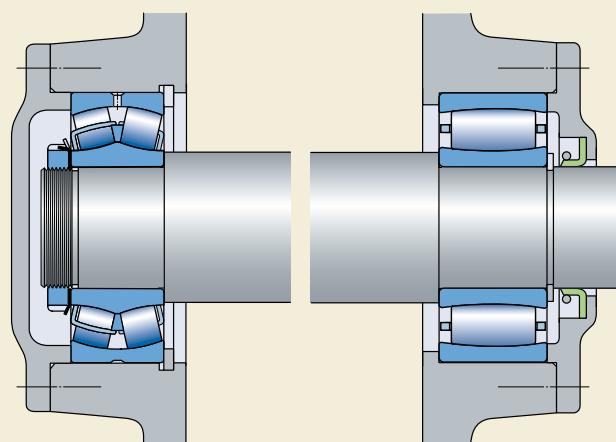

Fig. 2

SKF self-aligning bearing system using a spherical roller bearing in the locating position and a CARB bearing in the non-locating position

Axial location of bearings

An interference fit alone is generally not adequate to locate a spherical roller bearing ring axially. As a rule, some suitable means of axially securing the ring is needed. Both rings of a locating bearing should be axially secured on both sides. For spherical roller bearings in the non-locating position, on the other hand, it is sufficient if the ring having the tighter fit – usually the inner ring – is axially secured; the other ring must be free to move axially relative to its seating (→ fig. 1 on page 21).

Bearing rings having an interference fit are generally mounted so that the ring abuts a shoulder on the shaft or in the housing on one side. On the opposite side, inner rings are normally secured by a snap ring, shaft nut or an end plate attached to the shaft end. Outer rings are usually retained by the housing end cover (→ fig. 1 on page 21).

The dimensions of the shaft and housing shoulders adjacent to the bearing must provide sufficient support for the bearing rings, without making contact with rotating parts of the bearing or a stationary component. To keep this from happening, appropriate abutment dimensions are quoted for each individual bearing listed in the product tables.

If a sealed bearing is secured axially on the shaft by a lock nut, SKF recommends using a KMFE lock nut or an intermediate ring positioned between the bearing and the lock nut (→ fig. 3).

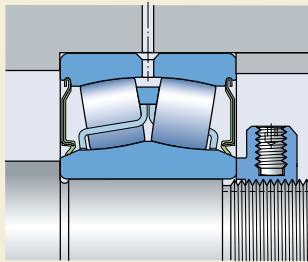

Design of associated components

For arrangements with large spherical roller bearings it is often necessary to make design provisions that enable the bearings to be mounted or dismounted easily. For example, withdrawal tools can be used to dismount bearings, if appropriate slots are machined in the shaft and housing shoulders, or if threaded holes are provided in the housing shoulders.

If the oil injection method is to be used to mount and dismount bearings on tapered journals (→ fig. 4) or to dismount bearings from cylindrical seatings (→ fig. 5), it is necessary to provide an oil supply duct in the journal and a groove in the seating. Recommendations are provided in the SKF General Catalogue and online in the SKF Interactive Engineering Catalogue at www.skf.com.

Fig. 5

Lubrication and maintenance

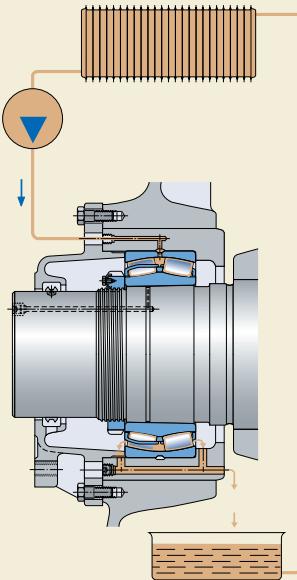

Fig. 1

Spherical roller bearing application lubricated by an oil bath

Spherical roller bearing application lubricated by circulating oil

Fig. 2

Oil lubrication

When oil is the lubricant, the oil bath or oil recirculating methods are the two most common.

Oil bath

This is the most simple method of oil lubrication (→ fig. 1). The oil, which is picked up by the rotating components of the bearing, is distributed within the bearing and then flows back to the oil sump.

The oil level should be such that it almost reaches the centre of the lowest roller when the bearing is stationary. Even under optimum operating conditions, the oil must be changed at least once a year.

Circulating oil

In a recirculating system, the oil can be continuously filtered and/or cooled (→ fig. 2). This significantly increases the service life of the oil, helping to avoid frequent oil changes.

The circulation can be produced by a pump. In a recirculating system, ducts must be adequately dimensioned so that the oil exits from the housing after passing through the bearing.

An intermediate form of oil circulation is one where the oil is splashed up from the oil bath by other components, e.g. gears in a gearbox.

Grease lubrication

Today's modern greases enable an increasing number of maintenance-free bearing applications to be lubricated for life. Here, the selection of sealed SKF spherical roller bearings is the optimum choice, both technically and economically. These bearings are filled with SKF LGEP 2 grease with a lithium thickener, before leaving the factory (→ table 1) and are ready to mount and operate.

In cases where the operating conditions are so harsh that very frequent relubrication is needed or where sealed SKF spherical roller

bearings are not available, SKF offers a full range of greases and tools to enable proper lubrication of the bearing (→ section "Lubricants and lubrication equipment" on page 66).

Relubrication

It is only possible to determine relubrication intervals statistically. SKF bases its relubrication intervals on the time at which 99 % of a seemingly identical lot of bearings are still reliably lubricated, i.e. they correspond to an L_{10} grease life which is the relubrication interval t_f . The L_{10} grease life is approximately twice the L_1 life.

If the L_{10} grease life corresponds to, or exceeds, the L_{10} life of the bearing, the bearing is considered to be lubricated for life and relubrication is not required.

The following recommendations are based on the results of long-term tests in various applications. They do not apply where water and/or particulate contaminants can penetrate

Table 1

Technical data for SKF LGEP 2 grease	
Property	SKF LGEP 2 grease
Thickener	Lithium
Colour	Light brown
Base oil type	Mineral
NLGI consistency class	2
Temperature range, °C (°F) ¹⁾	-20 to +110 (-4 to +230)
Reference temperature, °C (°F)	60 (140)
Dropping point to ISO 2176, °C (°F)	min. 180 (356)
Base oil viscosity, mm ² /s at +40 °C	200
at +100 °C	6

¹⁾ The safe bearing operating temperature according to "The SKF traffic light concept", where the grease will function reliably, lies within +40 to +110 °C

the bearing arrangement. In such cases it is advisable to replenish or renew the grease fill in the arrangement more frequently to remove moisture or other contaminants.

Relubrication

The relubrication intervals t_f for bearings with a rotating inner ring on a horizontal shaft, operating under normal and clean conditions, can be obtained from **diagram 1** as a function of

- the speed factor A multiplied by the relevant bearing factor b_f where
 $A = n d_m$
 n = rotational speed, r/min
 d_m = bearing mean diameter
 $= 0,5 (d + D)$, mm
 b_f = bearing factor depending on
bearing type and load conditions
(→ **table 2**)
- the load ratio C/P.

The relubrication interval t_f is an estimated value, valid for an operating temperature of 70 °C, using good quality greases with a lithium thickener and mineral base oil. When bearing operating conditions differ, adjust the relubrication intervals obtained from **diagram 1**.

If the speed factor A exceeds a value of 70 % of the recommended limit (→ **table 2**), or if ambient temperatures are high, one must check the operating temperature and determine whether the appropriate lubricant was applied. This can be done by using the calculations and graphs provided in the SKF General Catalogue, section "Speeds and vibration".

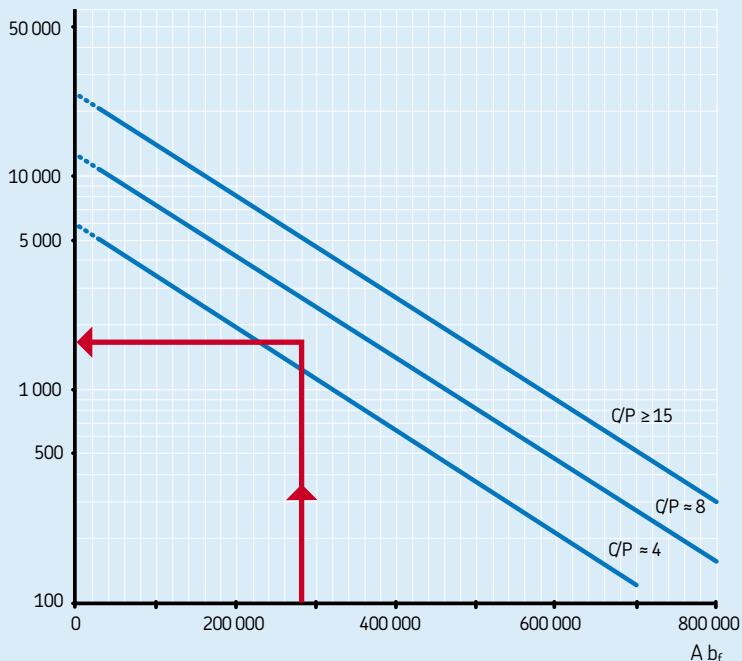

When using high performance greases, longer relubrication intervals and extended grease life may be possible. Contact the SKF application engineering service for additional information.

For additional information about grease lubrication, see the SKF General Catalogue or the SKF Interactive Engineering Catalogue online at www.skf.com.

Diagram 1

Relubrication intervals for grease lubricated spherical roller bearings

t_f , operating hours

Example

A spherical roller bearing 22220 E rotates at 1 000 r/min. The operating temperature varies between 60 and 70 °C (140 and 158 °F). The equivalent dynamic bearing load $P = 71$ kN and $F_a/F_r < e$. What is the correct lubrication interval? The bearing table on **page 38** lists: $d = 100$ mm, $D = 140$ mm, $C = 425$ kN. Bearing mean diameter $d_m = (100 + 140)/2 = 120$ mm. Bearing factor $b_f = 2$. Speed factor $A = 140\ 000$ (i.e. within recommended limit). A b_f is 280 000. $C/P = 425/71 = 6$.

Follow the line in **diagram 1**, from 280 000 on the $A b_f$ axis to the intersection with $C/P = 6$ (extrapolated). Continue horizontally from this intersection to the t_f axis, which shows the final result – a recommended relubrication interval of approximately 2 000 hours.

Table 2

Bearing factors and recommended limits for speed factor A

Bearing type	Bearing factor b_f	Recommended limits for speed factor A for load ratio		
		$C/P \geq 15$	$C/P \approx 8$	$C/P \approx 4$
–	–	mm/min		
Spherical roller bearings				
– when load ratio $F_a/F_r < e$ and $d_m \leq 800$ mm				
series 213, 222, 238, 239	2	350 000	200 000	100 000
series 223, 230, 231, 232, 240, 248, 249	2	250 000	150 000	80 000 ¹⁾
series 241	2	150 000	80 000 ¹⁾	50 000 ¹⁾
– when load ratio $F_a/F_r < e$ and $d_m > 800$ mm				
series 238, 239	2	230 000	130 000	65 000
series 230, 231, 232, 240, 248, 249	2	170 000	100 000	50 000
series 241	2	100 000	50 000 ¹⁾	30 000 ¹⁾
– when load ratio $F_a/F_r > e$				
all series	6	150 000	50 000 ¹⁾	30 000 ¹⁾

¹⁾ For higher speeds oil lubrication is recommended

Grease quantity for periodic relubrication

Initially, the bearing should be completely filled, while the free space in the housing should be partly filled. Depending on the intended method of replenishment, the following grease fill percentages for the free space in the housing are recommended:

- 40 % when replenishing from the side of an open bearing.
- 20 % when replenishing through the annular groove and lubrication holes in the bearing outer ring.

Suitable quantities for replenishment from the side of an open bearing can be obtained from

$$G_p = 0,005 D B$$

and for replenishment through the bearing outer or inner ring from

$$G_p = 0,002 D B$$

and for sealed bearings from

$$G_p = 0,0015 D B$$

where

G_p = grease quantity to be added when replenishing, g

D = bearing outside diameter, mm

B = total bearing width, mm

The bearing must rotate during relubrication to achieve proper distribution of the grease.

Grease quantity for continuous relubrication

The grease quantity to be continuously supplied can be obtained from

$$G_k = (0,3 \dots 0,5) D B \times 10^{-4}$$

where

G_k = grease quantity to be continuously supplied, g/h

D = bearing outside diameter, mm

B = total bearing width, mm

Continuous relubrication can be efficiently achieved using a SYSTEM 24® lubricator.

Relubrication of sealed SKF spherical roller bearings

The sealed spherical roller bearings shown in the product tables (starting on **page 56**) have an annular groove and three lubrication holes as standard. To prevent the penetration of moisture, and to retain the grease in the bearing, a polymer band in the groove covers the lubrication holes (**→ fig. 3**).

If it is anticipated that bearing relubrication will be necessary during operation, the band should be removed before the bearing is mounted. When relubricating, grease should be applied slowly to the bearing as it rotates until fresh grease emerges from the sealing lips. Excess pressure should be avoided to prevent seal damage.

For additional details, see the SKF General Catalogue or the SKF Interactive Engineering Catalogue online at www.skf.com.

A polymer band in the annular groove covers the lubrication holes in the outer ring of sealed bearings

Retaining rings hold the seals in the outer ring

Fig. 3

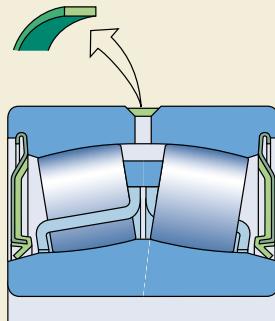

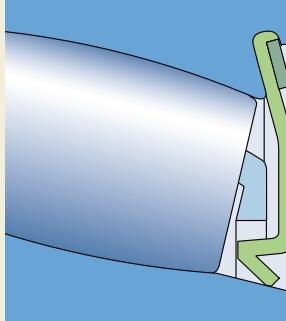

Fig. 4

Maintenance

The seals of SKF spherical roller bearings with a bore diameter ≥ 110 mm are secured by retaining rings inserted in the outer ring (→ fig. 4). The seals can be removed from the bearing so that the bearing can be inspected, washed and regreased, after which the seals can be reinserted and secured. To avoid damage to the seals, this work should be done with care, using blunt tools with no sharp edges.

1. Remove the retaining ring by inserting a tool under the recessed end of the retaining ring (→ fig. 5) and pushing it out of the groove.
2. Remove the second retaining ring as above.
3. Swivel the inner ring, so that the seals are pushed out by the rollers.
4. Wash the bearing, seals and retaining rings.
5. Inspect all parts for wear and damage.
6. Regrease the bearing with the inner ring swivelled out.
7. Align the bearing parts and put the bearing on a clean surface for remounting the seals.
8. Insert the seal as far as possible into its groove in the outer ring. Hold down the already inserted part of the seal with one hand, press in the remainder stepwise with the thumb of the other hand (→ fig. 6).

9. Mount the retaining ring by inserting the rectangular end first. Holding this part down, press in the remainder stepwise with a tool, until the whole retaining ring properly contacts the seal as shown in fig. 4
10. Mount the second seal according to steps 7 to 9.
11. If the bearing is not going to be reused immediately, apply oil to all surfaces and make sure that the bearing is packed properly.

B

Attention

SKF sealed spherical roller bearings can be supplied with different seals. Particular attention is needed for high temperature seals made of fluoro rubber (suffix 2CS2). The fluoro rubber (FKM) of SKF seals is very stable and harmless under normal operating conditions – up to +200 °C (392 °F). However, if exposed to extreme temperatures above +300 °C (572 °F), e.g. fire or the flame of a cutting torch, fluoro rubber emits dangerous toxic vapours. Once overheated the fluoro rubber will remain dangerous to handle even after it has cooled.

Removing a retaining ring

Inserting the seal in the outer ring

Mounting and dismounting

Bearing storage

Before leaving the factory, SKF spherical roller bearings are treated with a corrosion inhibitor. They can be stored in their unopened original packages for up to five years (three years for sealed bearings), provided the relative humidity in the store does not exceed 60 % (**→ fig. 1**).

To avoid the risk of contamination and corrosion, the original packages should not be opened until immediately before mounting the bearing.

Mounting

Skill and cleanliness are essential when mounting bearings, to make sure that they perform satisfactorily and attain their full potential. Above all, the appropriate mounting method should be chosen and suitable tools used. This is particularly important, where sealed SKF spherical roller bearings are concerned, since misalignment of the inner ring relative to the outer ring in excess of 0,5° may damage the seals. For optimum results in mounting and dismounting bearings, SKF offers a full range of tools and equipment. Please refer to the section "Related SKF products" starting on **page 64**.

Bearings with a cylindrical bore

When mounting bearings with a cylindrical bore, the ring with the tighter fit is normally mounted first.

The force required to mount a bearing increases with bearing size. Therefore, it is not always possible to press large bearings onto a cylindrical shaft or into a housing in the cold state. In this case, either the inner ring or the housing should be heated before mounting.

To mount with an interference fit on a shaft the bearing should be heated to some 80 to 90 °C (140 to 160 °F) above the temperature of the shaft. Please remember that sealed bearings should never be heated to more than 110 °C (230 °F).

The use of an SKF induction heater (**→ fig. 2**) has a number of advantages. It heats the bearing rapidly, and a built-in thermostat prevents overheating, which otherwise could damage the bearing. Non-metallic components such as seals remain cold, as does the heater itself.

Mounting bearings by cooling the shaft or the bearing is not recommended, as the very low temperatures required inevitably cause condensation, thus creating a risk of corrosion.

Correct storage of bearings

SKF induction heater

Bearings with a tapered bore

Bearings with a tapered bore are always mounted with an interference fit on the shaft. They can be mounted on adapter or withdrawal sleeves or directly onto tapered journals.

When dimensioning a tapered journal, the distance between the centre of the bearing in its final mounted position and a reference face on the shaft should be used as a basis (→ fig. 3). When the dimension B_a has been established, the dimensioning of the journal should be continued as described in the SKF catalogue 4003 "Large bearings".

Spherical roller bearings up to a 200 mm bore diameter may be driven up onto a tapered journal or a withdrawal sleeve using a shaft nut and onto an adapter sleeve using the sleeve nut and a spanner (→ fig. 4).

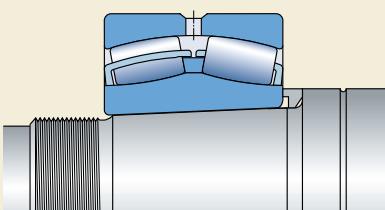

In applications with larger bearings, heavy drive-up forces are required. Mounting can be facilitated using the oil injection method (→ fig. 5). This requires an oil supply duct in the journal and an oil distribution groove in the bearing seating. To further reduce mounting effort, SKF recommends using the oil injection method in combination with an SKF hydraulic nut (→ fig. 8).

For a bearing that will be mounted hot, its final axial position on the shaft must be predetermined. This can be done by means of a tailor-made spacer ring (→ fig. 6). When the bearing has cooled, it will obtain its correct interference fit.

The reduction in radial internal clearance of open bearings or the axial displacement of the inner ring on its tapered seating is used as a measure of the degree of interference (→ fig. 7).

Fig. 7

Dimensioning of a tapered journal

Fig. 3

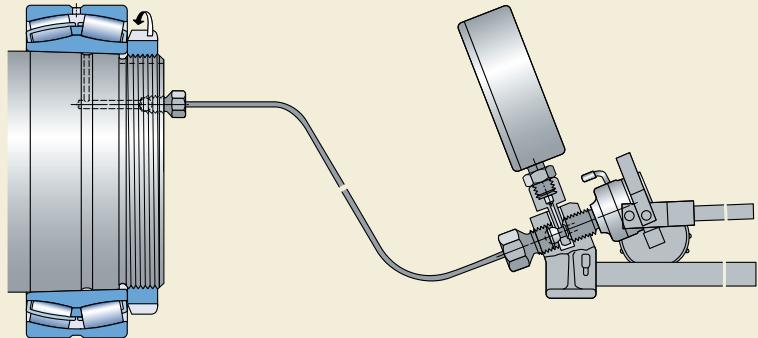

Mounting of a medium sized bearing

Fig. 4

Fig. 5

Drive-up of a large size bearing using the oil injection method

Using traditional methods, the only way to accurately mount sealed bearings with a tapered bore, is to use the drive-up distance as a measure. However, SKF has devised two additional methods that make installation accurate and fast. The first is the SKF Drive-up Method. This method allows a starting position of the bearing to be easily and accurately determined by applying a well-defined oil pressure to a hydraulic nut. The correct fit is then achieved by controlling the axial drive-up from this position.

The SKF Drive-up Method incorporates the use of a hydraulic nut fitted with a dial indicator to control the drive-up and a specially calibrated pressure gauge, mounted on the selected pump (**→ fig. 8**).

The second method of installation is to use SensorMount®. SensorMount which uses electronics to control the inner ring drive-up, is easy to use, fast, reliable and does not require special mounting skills.

The system comprises a bearing with a sensor and a hand-held indicator. A signal from the sensor is picked up by the indicator which displays a value representing the internal clearance reduction (**→ fig. 9**).

As the indicator displays what is actually happening with the bearing, it does not matter what material the seating is made of or whether the shaft is solid or hollow. No additional calculations or tables are needed to achieve the proper drive-up distance.

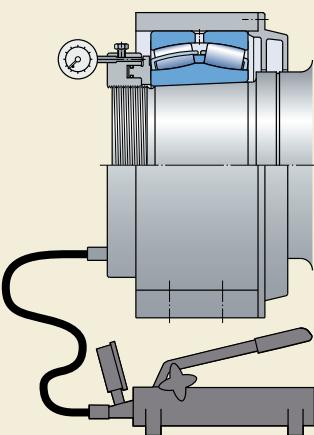

SensorMount is available for medium and large size bearings.

Additional information about mounting spherical roller bearings, the SKF Drive-up Method or SensorMount can be found

- in the SKF Interactive Engineering Catalogue online at www.skf.com
- online at www.skf.com/mount.

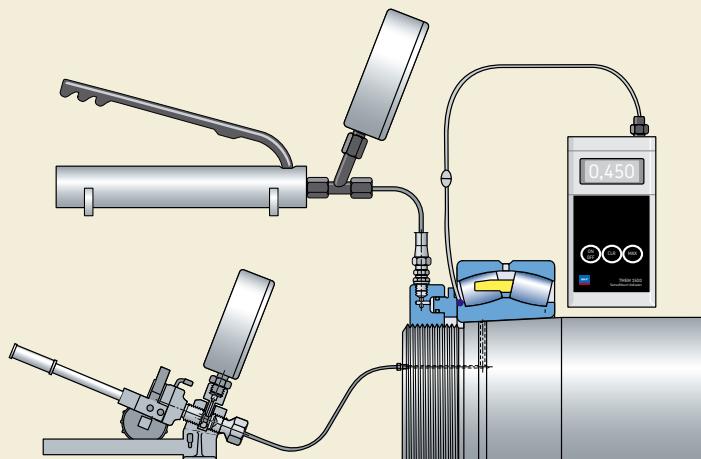

Mounting a bearing using the SKF Drive-up Method

Fig. 8

Mounting a bearing using the SensorMount method

Fig. 9

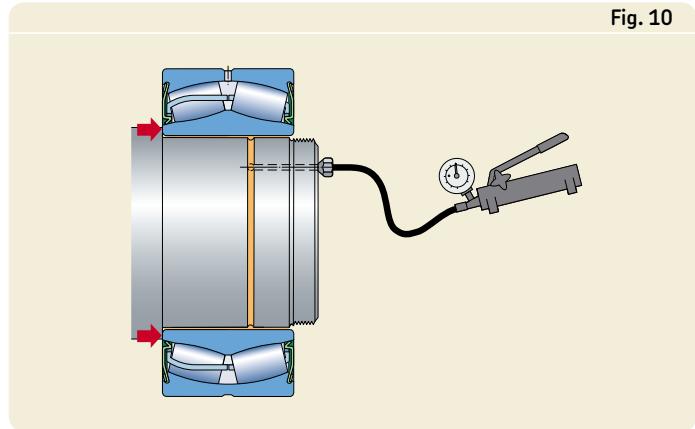

Fig. 10

Dismounting a bearing from a cylindrical seating using the oil injection method

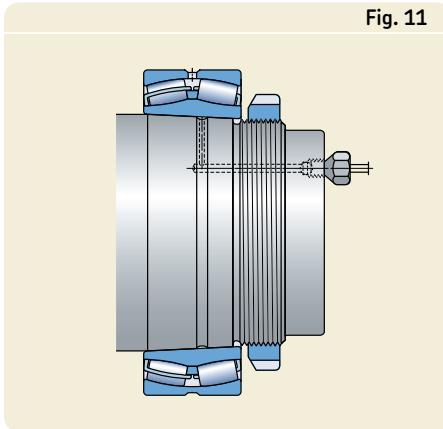

Fig. 11

Dismounting a bearing from a tapered journal using the SKF oil injection method

Dismounting

The force required to remove a bearing from its seating is generally greater than the mounting force, particularly if, after a long period of service, fretting corrosion is present. If bearings or other associated components are to be reused after inspection, they must be dismounted as carefully as they were mounted, and the dismounting force should never be applied through the rolling elements.

Bearings with a cylindrical bore

Small bearings can generally be removed using a mechanical puller. The withdrawal tool should grip over the rings from the inside or outside and contact the side faces.

When bearings with a bore diameter ≥ 80 mm have been mounted on a shaft with an interference fit, dismounting is considerably easier when the SKF oil injection method is used (→ fig. 10).

Bearings with a tapered bore

To remove spherical roller bearings from tapered journals, the oil injection method is recommended (→ fig. 11). The film of pressurised oil separates the two mating surfaces and makes the bearing slide off easily.

Bearings mounted on adapter or withdrawal sleeves are most easily removed using a hydraulic nut (→ fig. 12). By using sleeves with oil ducts and oil distribution grooves, the oil injection method facilitates the removal of large bearings (→ fig. 13).

Safety note

When using the oil injection method to dismount a bearing from a tapered seating, be sure to block the end of the shaft with a lock nut or other suitable device to prevent the bearing from falling.

Additional information about dismounting spherical roller bearings can be found

- in the SKF Interactive Engineering Catalogue online at www.skf.com
- online at www.skf.com/mount.

Bearing data – general

Designs

Depending on the size and series, SKF spherical roller bearings incorporate one of the internal designs shown below. Common features of all designs include symmetrical rollers and a floating guide ring between the roller rows. The arrangement of the guide ring as well as the cage execution are different for the various designs.

E design ($d \leq 65$ mm)

Guide ring centred on the inner ring, two window-type steel cages.

E design ($d > 65$ mm)

Guide ring centred on the cages, two window-type steel cages.

EJA design

Guide ring centred on the outer ring, two window-type steel cages.

C, CC, EC and ECC designs

Guide ring centred on the inner ring, two window-type steel cages.

CCJA design

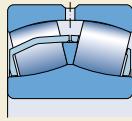

Guide ring centred on the outer ring, two window-type steel cages.

CA, CAF, ECA and ECAF designs

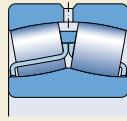

Guide ring centred on the inner ring, retaining flanges on the inner ring, one-piece machined cage of brass or steel (suffix F).

CAFA and CAMA designs

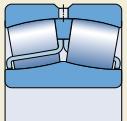

Guide ring centred on the inner ring, retaining flanges on the inner ring, one-piece machined cage of steel (CAFA) or brass (CAMA).

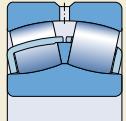

E design
 $d \leq 65$ mm

E design
 $d > 65$ mm

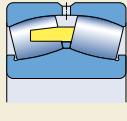

EJA design

C, CC, EC and
ECC designs

CCJA design

and ECAF designs

SKF Explorer

The designations of SKF Explorer bearings are printed in blue in the product tables.

Cylindrical or tapered bore

SKF spherical roller bearings are available with either a cylindrical or tapered bore. The tapered bore of bearings in the 240, 241, 248 and 249 series is 1:30. The tapered bore of bearings in the other series is 1:12.

Annular groove and lubrication holes

Efficient lubrication of SKF spherical roller bearings is facilitated by either

- three lubrication holes and an annular groove (E design or suffix W33) or
- three lubrication holes without annular groove (suffix W20).

Dimensions

The boundary dimensions of SKF spherical roller bearings with or without seals are in accordance with ISO 15:1998, except for the width of sealed bearings in the BS2-22 series. These are basically bearings in the 222 E or 222 CC series, but are slightly wider to integrate the seals.

Tolerances

SKF spherical roller bearings are manufactured as standard to Normal tolerances.

SKF Explorer spherical roller bearings up to and including 300 mm bore diameter are,

however, produced to higher precision than the ISO Normal tolerances. For example

- the width tolerance is considerably tighter than the ISO Normal tolerance (→ SKF General Catalogue 6000)
- the running accuracy is to P5 tolerance class as standard.

For applications with larger bearings where running accuracy is a key operational parameter, SKF spherical roller bearings with P5 running accuracy are also available. These bearings are identified by the suffix C08. Contact SKF for availability.

The tolerance for the bore and the outside diameter of SKF Explorer spherical roller bearings for vibratory applications has been tightened from Normal to P5 and P6 respectively.

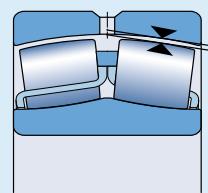

The values of the tolerances are in accordance with ISO 492:2002.

Internal clearance

SKF spherical roller bearings are manufactured as standard with Normal radial internal clearance. Nearly all the bearings are also available with a larger C3 internal clearance and some can be supplied with an even larger C4 or C5 clearance. Some sizes can be delivered with C2 internal clearance which is smaller than Normal. Contact SKF for availability of bearings with radial internal clearance other than Normal before ordering. The various radial internal clearances are in accordance with ISO 5753:1991 and shown in **tables 1** and **2**. They are valid for zero measuring load before mounting.

Misalignment

The design of spherical roller bearings is such that they are inherently self-aligning, i.e. angular misalignment between the outer ring and inner ring can be accommodated without any negative effect on bearing performance. Under normal operating conditions, i.e. load ratios of $C/P > 10$ and misalignment is constant in position instead of relative to the outer ring, the guideline values for permissible misalignment of open bearings provided in **table 3** apply. Whether or not these values can be fully exploited depends on the design of the bearing arrangement, the type of external seals used etc.

When the position of misalignment is not constant with respect to the bearing outer ring, e.g. in

- vibrating screens with rotating imbalance and therefore rotating deflection of the shaft (→ **fig. 1**)
- deflection-compensating rolls of paper machines where the stationary shaft is bent

additional sliding can occur in the bearing. Therefore, taking bearing friction and associated heat generation into consideration, misalignment of the inner ring relative to the outer ring should not exceed a few tenths of a degree.

Sealed bearings can accommodate angular misalignment of the shaft relative to the housing of up to $0,5^\circ$ with no detrimental effect on the efficiency of the seals.

Influence of operating temperature on the bearing materials

SKF spherical roller bearing rings and rollers undergo a unique heat treatment process so that they can withstand temperatures up to $+200^\circ\text{C}$ (390°F) for up to 2 500 hours, or brief periods at even higher temperatures, without any inadmissible dimensional changes occurring. If provision is made to accommodate slight changes of fits and clearance, even higher temperatures or longer periods can be accommodated.

Sealed SKF spherical roller bearings with standard seals and grease should not be used at operating temperatures above $+110^\circ\text{C}$ (230°F) as this would be detrimental to the seals and grease.

Axial load carrying capacity

Because of their special internal design, SKF spherical roller bearings not only have lower friction than other spherical roller bearings, but they are also able to accommodate appreciably heavier axial loads. However, if $F_a/F_T > e$ (→ **product tables**), more frequent lubrication is recommended.

Speed ratings

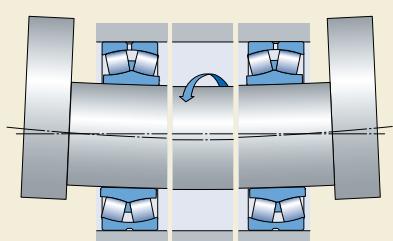

Due to the friction generated by contact seals, the speed rating for a sealed bearing operating within the normal temperature range is approximately 40 % less than for a corresponding open bearing.

Supplementary designations

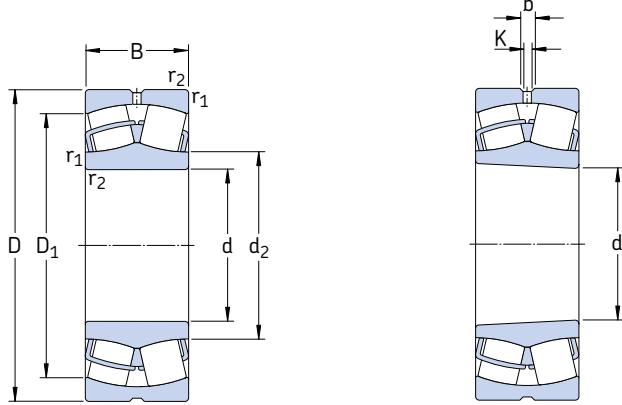

The designation suffixes used to identify certain features of SKF spherical roller bearings are explained below.

C2	Radial internal clearance smaller than Normal	VE553(E)	Outer ring with three equally spaced threaded holes in both side faces to accommodate hoisting tackle; the E indicates that appropriate eye bolts are supplied with the bearings
C3	Radial internal clearance greater than Normal	VG114	Surface hardened pressed steel cages
C4	Radial internal clearance greater than C3	VQ424	Running accuracy better than C08
C5	Radial internal clearance greater than C4	VT143	Grease fill 25 to 35 % with SKF LGEP 2 grease
C08	Increased running accuracy to ISO tolerance class 5	W	No relubrication facility in the outer ring
C083	C08 + C3	W20	Three lubrication holes in the outer ring
C084	C08 + C4	W26	Six lubrication holes in the inner ring
2CS	Sheet steel reinforced contact seal of acrylonitrile-butadiene rubber (NBR) on both sides of the bearing. Grease fill 25 to 35 % with SKF LGEP 2 grease. Annular groove and three lubrication holes in the outer ring.	W33	Annular groove and three lubrication holes in the outer ring
2CS2	Sheet steel reinforced contact seal of fluoro rubber (FPM) on both sides of the bearing. Grease fill 70 to 100 % with a polyurea high temperature grease. Annular groove and three lubrication holes in the outer ring	W64	Solid Oil filling
2CS5	Sheet steel reinforced contact seal of hydrogenated acrylonitrile-butadiene rubber (HNBR) on both sides of the bearing. Grease fill 70 to 100 % with a polyurea high temperature grease. Annular groove and three lubrication holes in the outer ring	W77	Plugged W33 lubrication holes
HA3	Case hardened inner ring	W513	W26 + W33
K	Tapered bore, taper 1:12	235220	Case hardened inner ring with a helical groove in the bore
K30	Tapered bore, taper 1:30		
P5	Dimensional and running accuracy to ISO tolerance class 5		
P6	Dimensional and running accuracy to ISO tolerance class 6		
P62	P6 + C2		
VA405	Bearing for vibratory applications		
VA406	Bearing for vibratory applications with PTFE-coated bore		
VE552(E)	Outer ring with three equally spaced threaded holes in one side face to accommodate hoisting tackle; the E indicates that appropriate eye bolts are supplied with the bearings

Related SKF products

Special spherical roller bearings

Their robust design and high reliability make SKF spherical roller bearings suitable for the majority of applications. However, extraordinary demands call for bearings with extraordinary features. Therefore, the SKF standard range includes special spherical roller bearings, which are adapted for specific applications:

Sealed bearings for continuous casting applications

These bearings are specially adapted for the heavy loads and high operating temperatures and low speeds present in continuous casting slab guides. They feature seals made of fluoro rubber, and are filled with a very stable high temperature grease, enabling maintenance-free operation in this demanding environment.

Rolling mill bearings

Rolling mill bearings must meet a variety of different demands. For cold tube mills (Pilger mills), for example, the bearings must be able to withstand heavy acceleration forces, whereas for finishing trains or wire mills, they must be able to be mounted and dismounted with ease. SKF offers the appropriate spherical roller bearings for these applications.

See also SKF brochures 4954 "The SKF Copperhead system solution for vibrating screens" and 6103 "SKF ConCentra roller bearing units – true concentric locking, for fast and reliable mounting".

SKF ConCentra bearing units

These plummer block type mounted bearing units with SKF Explorer spherical roller bearings in the 222 series on a special adapter sleeve are greased, sealed and ready to install as delivered. With the saw-tooth profile of the inner ring and adapter sleeve, the unit can be mounted and dismounted easily via the incorporated screws without having to use special tools.

Accessories

Any system is only as strong as its weakest component. Therefore, SKF offers not only a wide range of high quality spherical roller bearings, but also an appropriate range of quality bearing accessories to go with them.

Bearing housings

SKF offers a comprehensive range of high-quality standard and custom housings designed to accommodate the various demands placed on the bearings which they house, e.g. load, accuracy, method of lubrication, type of lubricant, sealing etc.

SKF housings and SKF spherical roller bearings form an economic and interchangeable unit which meets the performance demands of a bearing application.

See also SKF catalogues 6005 and 6006 for detailed information about bearing sleeves and lock nuts respectively and SKF brochures 6112 "SNL plummer block housings solve the housing problems", 6101 "SNL 30 and SNL 31 plummer block housings solve the housing problems" and 6111 "SONL plummer block housings designed for oil lubrication".

Adapter and withdrawal sleeves

Adapter and withdrawal sleeves are used to locate bearings with a tapered bore on smooth or stepped shafts. They facilitate bearing mounting and dismounting and, in many cases, simplify bearing arrangement design. Several series of quality sleeves are included in the SKF product range.

SKF withdrawal and adapter sleeves

D

Lock nuts

SKF lock nuts, also referred to as shaft nuts, are available in several designs to axially locate bearings on shaft ends. The most popular are those in the KM, KML and HM series. These nuts have four or eight equally spaced slots in the outside diameter and are locked in position with locking washers or locking clips engaging a groove in the shaft. The nut dimensions are in accordance with ISO 2982-2:1995, as are the dimensions of the series MB and MBL locking washers.

Other lock nuts produced by SKF include lock nuts in the KMT, KMTA, KMK and KMFE series, that do not require a groove in the shaft.

SKF lock nuts

Lubricants and lubrication equipment

Spherical roller bearings are required to operate under a variety of load, speed, temperature and environmental conditions. They require the type of high-quality lubricating greases, which SKF provides.

SKF greases have been specially developed for rolling bearings in their typical applications. The SKF range includes fifteen environmentally friendly greases and covers practically all application requirements.

The range is complemented by a selection of lubrication accessories including

- automatic lubricators
- grease guns
- lubricant metering devices
- a wide range of manually and pneumatically operated grease pumps.

Products for mounting and dismounting

Like all rolling bearings, SKF spherical roller bearings require a high degree of skill when mounting or dismounting, as well as the correct tools and methods.

The comprehensive SKF range of tools and equipment includes everything that is required

- mechanical tools
- heaters
- hydraulic tools and equipment
- pullers and withdrawal tools for all bearing sizes.

SKF Drive-Up Method

www.mapro.skf.com.**

**SKF lubricants:
the best choice for any bearing**

Condition monitoring equipment

The goal of condition monitoring is to maximize uptime, minimize unplanned downtime and reduce maintenance.

To achieve this, SKF recommends monitoring the bearing and other machine components either periodically or continuously. Condition monitoring enables incipient bearing damage to be detected and evaluated, so that bearing replacement can be scheduled for a time when the machine is not in operation, to avoid unplanned stoppages. Applied to all machinery (not just sensitive or problematic machines), condition monitoring optimizes machinery utilization, often exceeding the original equipment projections for service life.

SKF provides a comprehensive range of condition monitoring equipment to measure all important parameters. These include

- temperature
- speed
- noise
- oil condition
- shaft alignment
- vibration
- bearing condition.

Products range from lightweight, handheld devices, to sophisticated continuous monitoring systems for fixed installations that can be integrated into an existing proactive reliability maintenance programme.

One example is the MARLIN® I-Pro data manager, which is a rugged, high performance data collector that enables plant operations personnel to quickly and easily collect, store and analyze overall machine vibration, process and inspection data. The unit enables trending, comparison with previous readings, alarm alerts and more. A "user notes" feature allows an operator to immediately record detailed observations of troublesome machine conditions or questionable measurements.

SKF – the knowledge engineering company

From the company that invented the self-aligning ball bearing 100 years ago, SKF has evolved into a knowledge engineering company that is able to draw on five platforms to create unique solutions for its customers. These platforms include bearings, bearing units and seals, of course, but extend to other areas including: lubricants and lubrication systems, critical for long bearing life in many applications; mechatronics that combine mechanical and electronics knowledge into systems for more effective linear motion and sensorized solutions; and a full range of services, from design and logistics support to conditioning monitoring and reliability systems.

Though the scope has broadened, SKF continues to maintain the world's leadership in the design, manufacture and marketing of rolling bearings, as well as complementary products such as radial seals. SKF also holds an increasingly important position in the market for linear motion products, high-precision aerospace bearings, machine tool spindles and plant maintenance services.

The SKF Group is globally certified to ISO 14001, the international standard for environmental management, as well as OHSAS 18001, the health and safety management standard. Individual divisions have been approved for quality certification in accordance with either ISO 9000 or QS 9000.

With some 100 manufacturing sites worldwide and sales companies in 70 countries, SKF is a truly international corporation. In addition, our distributors and dealers in some 15 000 locations around the world, an e-business marketplace and a global distribution system put SKF close to customers for the supply of both products and services. In essence, SKF solutions are available wherever and whenever customers need them. Overall, the SKF brand and the corporation are stronger than ever. As the knowledge engineering company, we stand ready to serve you with world-class product competencies, intellectual resources, and the vision to help you succeed.

Evolving by-wire technology

SKF has a unique expertise in fast-growing by-wire technology, from fly-by-wire, to drive-by-wire, to work-by-wire. SKF pioneered practical fly-by-wire technology and is a close working partner with all aerospace industry leaders. As an example, virtually all aircraft of the Airbus design use SKF by-wire systems for cockpit flight control.

SKF is also a leader in automotive by-wire technology, and has partnered with automotive engineers to develop two concept cars, which employ SKF mechatronics for steering and braking. Further by-wire development has led SKF to produce an all-electric forklift truck, which uses mechatronics rather than hydraulics for all controls.

Harnessing wind power

The growing industry of wind-generated electric power provides a source of clean, green electricity. SKF is working closely with global industry leaders to develop efficient and trouble-free turbines, providing a wide range of large, highly specialized bearings and condition monitoring systems to extend equipment life of wind farms located in even the most remote and inhospitable environments.

Working in extreme environments

In frigid winters, especially in northern countries, extreme sub-zero temperatures can cause bearings in railway axleboxes to seize due to lubrication starvation. SKF created a new family of synthetic lubricants formulated to retain their lubrication viscosity even at these extreme temperatures. SKF knowledge enables manufacturers and end user customers to overcome the performance issues resulting from extreme temperatures, whether hot or cold. For example, SKF products are at work in diverse environments such as baking ovens and instant freezing in food processing plants.

Developing a cleaner cleaner

The electric motor and its bearings are the heart of many household appliances. SKF works closely with appliance manufacturers to improve their products' performance, cut costs, reduce weight, and reduce energy consumption. A recent example of this cooperation is a new generation of vacuum cleaners with substantially more suction. SKF knowledge in the area of small bearing technology is also applied to manufacturers of power tools and office equipment.

Maintaining a 350 km/h R&D lab

In addition to SKF's renowned research and development facilities in Europe and the United States, Formula One car racing provides a unique environment for SKF to push the limits of bearing technology. For over 50 years, SKF products, engineering and knowledge have helped make Scuderia Ferrari a formidable force in F1 racing. (The average racing Ferrari utilizes more than 150 SKF components.) Lessons learned here are applied to the products we provide to automakers and the aftermarket worldwide.

Delivering Asset Efficiency Optimization

Through SKF Reliability Systems, SKF provides a comprehensive range of asset efficiency products and services, from condition monitoring hardware and software to maintenance strategies, engineering assistance and machine reliability programs. To optimize efficiency and boost productivity, some industrial facilities opt for an Integrated Maintenance Solution, in which SKF delivers all services under one fixed-fee, performance-based contract.

Planning for sustainable growth

By their very nature, bearings make a positive contribution to the natural environment, enabling machinery to operate more efficiently, consume less power, and require less lubrication. By raising the performance bar for our own products, SKF is enabling a new generation of high-efficiency products and equipment. With an eye to the future and the world we will leave to our children, the SKF Group policy on environment, health and safety, as well as the manufacturing techniques, are planned and implemented to help protect and preserve the earth's limited natural resources. We remain committed to sustainable, environmentally responsible growth.
